## **Bayesian Statistics**

#### Introduction to Stan

Leonardo Egidi

A.A. 2018/19

Leonardo Egidi Introduction 1 / 52

What is Stan? ● Why Stan? ● Writing a Stan program ● Linked package: bayesplot

## Origins

Stanislaw Ulam (1909-1984): Manhattan project, H-Bomb experiments in Los Alamos, MCMC father jointly with John von Neumann.

Leonardo Egidi Introduction 2 / 52

• What is Stan? • Why Stan? • Writing a Stan program • Linked package: bayesplot •

#### What is Stan?

• Probabilistic programming language and inference algorithms.

- Stan program
  - declares data and (constrained) parameter variables
  - defines log posterior (or penalized likelihood)
- Stan inference
  - MCMC for full Bayes
  - Variational Bayes for approximate Bayes
  - Optimization for (penalized) MLE
- Stan ecosystem
  - lang, math library (C++)
  - interfaces and tools (R, Python, Julia, many more)
  - documentation (example model repo, user guide & reference manual),
     case studies, R package vignettes)

• online community ( Stan Forums on Discourse)

Leonardo Egidi Introduction 4 / 52

• What is Stan? • Why Stan? • Writing a Stan program • Linked package: bayesplot

## Why Stan?

• Fit rich Bayesian statistical models. Close to the big data philosophy.

- Efficiency
  - Hamiltonian Monte Carlo + NUTS
  - Compiled to C++
- Flexible domain specific language
- "Freedom-respecting, open-source"
  - doc & written materials
  - interacting community
  - continuous development
- Interaction with some other R packages designed to explore the Stan output.

Leonardo Egidi Introduction 5 / 52

What is Stan?
 Why Stan?
 Writing a Stan program
 Linked package: bayesplot

## Who is using Stan?

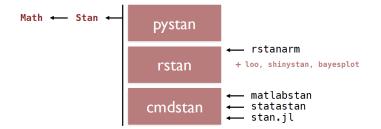

- Biological & physical sciences: clinical trials, epidemiology, genomics, population ecology, entomology, ophthalmology, neurology, agriculture, fisheries, cancer biology, astrophysics & cosmology, molecular biology, oceanography, climatology.
- Social sciences: population dynamics. psycholinguistics, social networks, political science, human development, economics.
- Many more: sports analytics, public health, publishing, finance, pharma, actuarial, recommender systems, educational testing, materials engineering.

## Improving MCMC performance

With Stan, we aim to provide an MCMC implementation that works robustly for as many target distributions as possible

- Gibbs, RW Metropoilis can be very inefficient, hard to diagnose.
- To explore complicated high-dimensional spaces we need to leverage what we know about the geometry of the typical set.
- For such a reason, Stan enjoys Hamiltonian Monte Carlo.

We will have now only a brief sketch about how HMC works (further readings are mentioned later on). The Stan users, however, may use, analyze and interpret HMC outputs as they were *standard* MCMC outputs!

Leonardo Egidi Introduction 9 / 52

Once we have built a model, Bayesian computation reduces to evaluating expectations, or integrals.

$$E_{\pi}(\theta|y) = \int \theta \pi(\theta|y) d\theta$$
 (1)

How do we compute posterior expectations in practice?

- Construct a Markov chain that explores the parameter space.
- Anything you would want to do if you could write it analytically, you can do to any accuracy with the draws (history) of the chain

$$\lim_{S\to\infty}\frac{1}{S}\sum_{s=1}^S\theta^{(s)}\to E_\pi(\theta|y)$$

Leonardo Egidi Introduction 10 / 52 • What is Stan? • Why Stan? • Writing a Stan program • Linked package: bayesplot

## Moving to Hamiltonian Monte Carlo

To be efficient we need to focus computation on the relevant neighborhoods of parameter space. Relevant neighborhoods, however, are defined not by probability density but rather by probability mass.

But exactly which neighborhoods end up contributing most to arbitrary expectations?

• ------

The neighborhoods around the maxima of probability distributions feature a lot of probability density, but, especially in a large number of dimensions, or in long tailed distributions, they do not feature much volume. In other words, the *sliver* size  $d\theta$  tends to be small there.

Leonardo Egidi Introduction 11 / 52

## The Geometry of High-Dimensional Spaces

Consider a rectangular partitioning centered around a distinguished point, such as the mode (example from Betancourt, 2017):

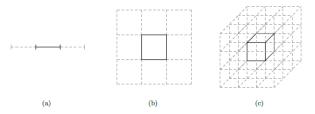

Fig 1. To understand how the distribution of volume behaves with increasing dimension we can consider a rectangular partitioning centered around a distinguished point, such as the mode. (a) In one dimension the relative weight of the center partition is 1/3, (b) in two dimensions it is 1/9, (c) and in three dimensions it is only 1/27. Very quickly the volume in the center partition becomes negligible compared to the neighboring volume.

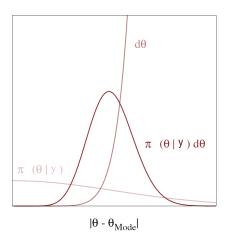

One of the characteristic properties of high-dimensional spaces is that there is much more volume outside any given neighborhood than inside of it!

Leonardo Egidi Introduction 12 / 52

What is Stan? • Why Stan? • Writing a Stan program • Linked package: bayesplot

### Typical set

Thus, relevant neighborhoods are defined not by probability density but rather by probability mass.

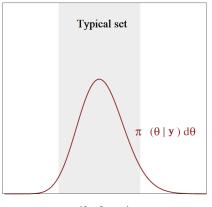

Leonardo Egidi Introduction 13 / 52

What is Stan? • Why Stan? • Writing a Stan program • Linked package: bayesplot •

### Typical set

Probability mass concentrates on a hypersurface called the typical set that surrounds the mode.

 $|\theta - \theta_{Mode}|$ 

Leonardo Egidi Introduction 14 / 52

● What is Stan? ● Why Stan? ● Writing a Stan program ● Linked package: bayesplot

## Moving to Hamiltonian Monte Carlo

To accurately estimate expectations we need a method for numerically finding and then exploring the typical set.

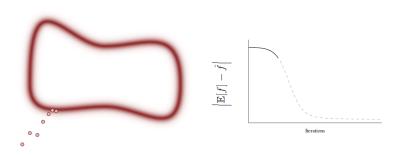

A Markov transition that targets our desired distribution naturally concentrates towards probability mass. An inherent inefficiency in the Gibbs sampler and in the random walk Metropolis Hastings is their random walk behaviour: the simulations can take a long time zigging and zagging while moving through the target distribution.

• ———•

HMC borrows strengths from physics to suppress the random walk behaviour in the Metropolis algorithm, thus allowing it to move much more rapidly through the target distribution. The method enjoys the gradient of the log-posterior distribution,  $\frac{d \log(\pi(\theta|y))}{d\theta}$  for a sort of adjustment of the algorithm towards the typical set area.

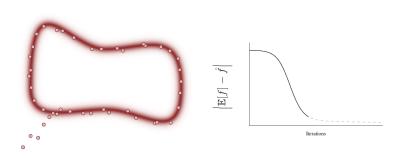

Leonardo Egidi Introduction 15 / 52

Under ideal conditions, MCMC estimators converge to the true expectations in a very practical progression.

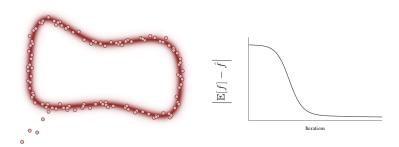

Leonardo Egidi 16 / 52

Under ideal conditions, MCMC estimators converge to the true expectations in a very practical progression.

Leonardo Egidi 17 / 52

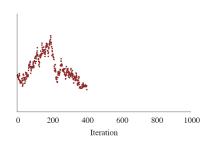

Under ideal conditions, MCMC estimators converge to the true expectations in a very practical progression.

Leonardo Egidi 18 / 52 • Why Stan? • Writing a Stan program • Linked package: bayesplot

### When something goes wrong

There are many pathological posterior geometries, however, that spoil these ideal conditions.

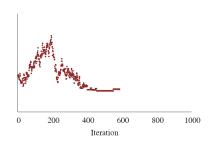

Leonardo Egidi Introduction 19 / 52

ideal conditions.

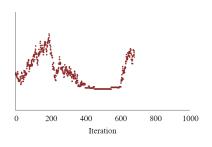

## There are many pathological posterior geometries, however, that spoil these

Leonardo Egidi Introduction 20 / 52

There are many pathological posterior geometries, however, that spoil these ideal conditions.

Leonardo Egidi Introduction 21 / 52

Vhat is Stan? • Why Stan? • Writing a Stan program • Linked package: bayesplot

#### Hamiltonian Monte Carlo

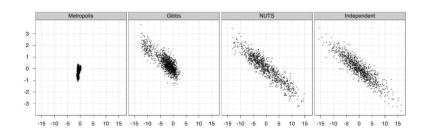

• Hamiltonian Monte Carlo yields fast, and *robust*, exploration of the distributions common in practice.

Leonardo Egidi Introduction 22 / 52

## Comparison of algorithms on **highly correlated** 250-dimensional Gaussian distribution

- •Do **1,000,000** draws with both Random Walk Metropolis and Gibbs, thinning by 1000
- •Do 1,000 draws using Stan's NUTS algorithm (no thinning)
- •Do 1,000 independent draws (we can do this for multivariate normal)

Leonardo Egidi Introduction 23 / 52

Leonardo Egidi Introduction 24 / 52

### Before starting

#### What is a Bayesian model?

- Building a Bayesian model forces us to build a model for how the data is generated
- We often think of this as specifying a prior and a likelihood, as if these are two separate things
- They are not!

Leonardo Egidi Introduction 25 / 52

#### Generative models

The philosophy behind Stan is to think generatively.

The model is expressed as a joint probability distribution of observed and unobserved variables, which may be decomposed as follows:

$$p(y,\theta) = p(y|\theta)\pi(\theta) \tag{2}$$

The posterior of interest is then proportional to the joint distribution (2):

$$p(\theta|y) \propto p(y|\theta)\pi(\theta)$$
 (3)

Leonardo Egidi 26 / 52 A Bayesian modeller commits to to an a priori joint distribution:

$$p(y,\theta) = \underbrace{p(y|\theta)\pi(\theta)}_{\textit{Likelihood} \times \textit{Prior}} = \underbrace{\pi(\theta|y)p(y)}_{\textit{Posterior} \times \textit{Marginal Likelihood}} \tag{4}$$

Leonardo Egidi 27 / 52

#### What is the problem with vague/diffuse priors?

- If we use an improper prior, then we do not specify a joint model for our data and parameters.
- More importantly, we do not specify a data generating mechanism p(y)
- By construction, these priors do not regularize inferences, which is quite often a bad idea
- Proper but diffuse is better than improper but is still often problematic.

Leonardo Egidi Introduction 28 / 52

#### Generative models

- If we disallow improper priors, then Bayesian modeling is generative.
- In particular, we have a simple way to simulate from p(y):

Leonardo Egidi 29 / 52 Stan works in logarithmic terms: all the computations are actually done on log-scale. So, for the posterior we have.

$$\log(\pi(\theta|y)) = \log(\pi(\theta)) + \log(p(y|\theta)) + \text{constant}$$
 (5)

Products become sums of logs:

$$p(y|\theta) = \prod_{i=1}^{n} p(y_i|\theta) \rightarrow \log(p(y|\theta)) = \sum_{i=1}^{n} \log(p(y_i|\theta)).$$

Leonardo Egidi Introduction 30 / 52

### Starting point

We are now going to write a Stan program together:

- Open a new empty file in RStudio
- Save it as linear\_regression.stan

Leonardo Egidi Introduction 31 / 52

Writing a Stan program Linked package: bayesplot

## Stan programs are organized into blocks:

• data block: declare data types, sizes, and constraints. Read from data

• parameters block: declare parameter types, sizes, and constraints. Evaluated: every log prob evaluation.

source and constraints validated. Evaluated: once.

- transformed parameters block: declare those parameters transformed from the original ones declared in the parameters block. Evaluated: every log prob evaluation.
- model block: statements defining the posterior density in log scale. Evaluated: every log prob evaluation.
- generated quantities: declare and define derived variables. (P)RNGs, predictions, event probabilities, decision making. Constraints validated. Evaluated: once per draw.

Leonardo Egidi Introduction 32 / 52

#### Data block

```
data {
 // Dimensions
 int<lower=1> N;
 int<lower=1> K;
 // Variables
 matrix[N, K] X;
 vector[N] y;
```

```
/* multiple lines of
comments */
```

Leonardo Egidi 33 / 52

```
parameters {
  real alpha;
  vector[K] beta;
  real<lower=0> sigma;
```

constraints required in parameters block

Leonardo Egidi 34 / 52

```
model {
  // priors (flat, uniform, if omitted)
  sigma \sim exponential(1);
  alpha \sim normal(0, 10);
  for (k \text{ in } 1:K) \text{ beta}[k] \sim \text{normal}(0, 5);
  for (n in 1:N) {
    y[n] \sim normal(X[n, ] * beta + alpha, sigma);
```

Why is the default automatically uniform?

- $\pi(\theta) \propto 1$  (0 on log scale)
- Nothing added to log prob

Leonardo Egidi Introduction 35 / 52

## Generated quantities block

```
generated quantities {
  vector[N] y_rep;
  for (n in 1:N) {
    real y_hat = X[n,] * beta + alpha; // local/temp
    v rep[n] = normal_rng(y_hat, sigma);
```

Leonardo Egidi 36 / 52

```
data {
  int<lower=1> N:
  int<lower=1> K:
  matrix[N, K] X;
  vector[N] v:
parameters {
  real alpha:
  vector[K] beta;
  real<lower=0> sigma;
model {
  sigma \sim exponential(1);
  alpha \sim normal(0, 10);
  for (k \text{ in } 1:K) \text{ beta}[k] \sim \text{normal}(0, 5):
  for (n in 1:N)
    y[n] ~ normal(alpha + X[n, ] * beta, sigma);
generated quantities {
  vector[N] y rep;
  for (n in 1:N)
    y_rep[n] = normal_rng(alpha + X[n,] * beta, sigma);
```

Observed variables

Unobserved variables

$$\log \pi(\theta) + \log p(y | \theta)$$

Simulate from generative model

Leonardo Egidi Introduction 37 / 52

```
Now we may launch the Stan program directly in R:
```

```
library(rstan)
# passing the data (already stored)
data <- list(N=N, K=K, X=X, y=y)
# fitting the model
fit1 <- stan(
  file = 'linear_regression.stan',
  data = data.
  iter = 2000,
  chains = 4)
# extracting the estimates
sims <- extract(fit1)
```

Leonardo Egidi Introduction 38 / 52

This example studied coaching effects from eight schools.

We denote with  $y_{ii}$  the result of the i-th test in the j-th school. We assume the following model:

$$y_{ij} \sim \mathcal{N}(\theta_j, \sigma_y^2)$$
  
 $\theta_j \sim \mathcal{N}(\mu, \tau^2)$ 

Do some schools perform better/worse according to these coaching effects? Here is the data, already aggregated by schools:

schools\_dat <- list(J = 8,  

$$y = c(28, 8, -3, 7, -1, 1, 18, 12),$$
  
 $sigma = c(15, 10, 16, 11, 9, 11, 10, 18))$ 

Leonardo Egidi Introduction 39 / 52

```
// saved as 8schools.stan
data {
 int<lower=0> J;  // number of schools
 real v[J];
             // estimated treatment effects
 real<lower=0> sigma[J]; // standard error of effect estimates
parameters {
 real mu;
                       // population treatment effect
 real<lower=0> tau; // standard deviation in treatment effects
 vector[J] eta;
               // unscaled deviation from mu by school
transformed parameters {
 vector[J] theta = mu + tau * eta;  // school treatment effects
model {
 eta \tilde{} normal(0,1);
                    // prior
 y ~ normal(theta, sigma); //likelihood
```

Leonardo Egidi 40 / 52 To fit the model and visualize the estimates, it is sufficient to type in R the following commands (with 2000 iterations and 4 chains as a default):

```
fit_8schools <- stan(file = '8schools.stan', data = schools_dat)</pre>
print(fit_8schools, pars=c("mu", "tau", "theta"))
```

```
2.5% 25% 50% 75% 97.5% n eff Rhat
               sd
         mean

```

Leonardo Egidi 41 / 52

- Writing a Stan program
- 4 Linked package: bayesplot

Leonardo Egidi 42 / 52 Once we fit a model, it is to vital check it via graphical inspection. The bayesplot package (for any help, see the vignette) is designed to this task.

The package allows to display:

- Posterior uncertainty intervals
- Univariate marginal posterior distributions
- Bivariate plots
- Trace plots
- Posterior predictive plots

Leonardo Egidi Introduction 43 / 52

### Posterior graphical analysis with bayesplot

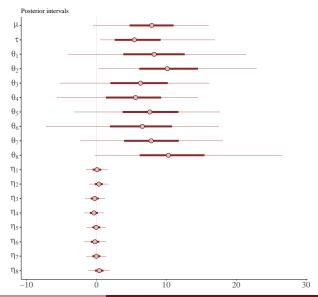

The first step is to save the posterior. Then you have many choices:

```
library(bayesplot)
posterior <- as.array(fit_8schools)</pre>
```

```
mcmc_intervals(posterior)
                              # posterior intervals
mcmc_areas(posterior)
                              # posterior areas
mcmc_dens(posterior)
                              # marginal posteriors
mcmc_pairs(posterior)
                              # bivariate plots
mcmc_trace(posterior)
                                trace plots
```

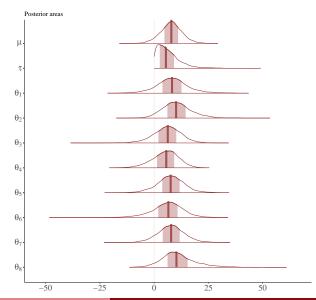

With the arguments pars or regex\_pars you may select the desired parameters.

Leonardo Egidi Introduction 47 / 52

## Marginal posteriors separated for each chain

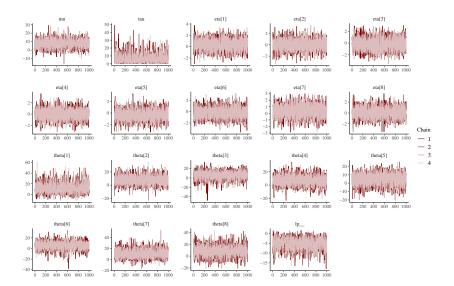

48 / 52 Leonardo Egidi

Leonardo Egidi 49 / 52

### Trace plots for the Markov chains

Leonardo Egidi 50 / 52

#### The Stan shuttle is ready to start! We will learn to:

- write simple and more complex model in Stan: Im, glm, hierarchical models.
- analyze the posterior summaries.
- criticize the model and, eventually, change/reparametrize it.

Leonardo Egidi 51 / 52
